1. Introduction

1.1 Research Problem

While it has become easy to develop a mobile health (mHealth) application (app), there is much more to it than just the aspects of the app's core functionality. Currently only very few guidelines, best practices and systematic development approaches for mobile app development can be found. Furthermore even less can be found for the specific area of mHealth apps.

Security leaks or even abuse of private and sensitive information¹⁰ can lead to great harm for the app user and to legal issues for the developer. Abuse of personal health related information can result in loss of reputation (e.g. sexual transmitted diseases) or financial drawbacks and decreased chances of employment (e.g. chronic diseases, genetic dispositions)¹¹. With poorly developed apps, there is a danger of security leaks and hence for data abuse. Thus the risk for app users increases. A study has shown that very few mHealth apps entail little or low risk for the app user.¹² Self-publishing through modern sales channels such as Google Play¹³ or the iOS App Store¹⁴ and the availability of easy-to-use Integrated Development Environments (IDEs) lower the barriers for entry. Even one-man developers or small teams are now able to publish apps easily with little development effort **TODO: CITE?**. Without fundamental knowledge of privacy and security aspects, there is an increase in the non-professional developmental of mobile apps with inadequate security aspects.

The usability, especially in critical situations, is another undervalued aspect in many non-professional developments **TODO: CITE**. While fancy colors might look appealing to

¹⁰ information, which is personal. Can be related to financial-, health- or otherwise personal relevant information, suggested by Future of Privacy Forum, Center for Democracy & Technology (2011), p. 6, although the definition varies

¹² cf. Njie (2013), pp. 19-20

¹³ <http://play.google.com>

¹⁴ <http://appstore.com>

the developer himself, it might lead to confusion for the app user or even to a lack of operability for visually impaired people.¹⁵ Also, the need for a intuitive user interface¹⁶ is not be considered as important as it should be.

Knowledge of data privacy acts and laws is a premise for a legal, safe and fair development for the developer and the app user. Multiple layers of data privacy laws in Europe on international, national and state level require a certain legal knowledge.¹⁷ Also, the benefit of and the need for a privacy policy seems to be ambiguous for many non-professional developers.¹⁸

This lack of guidelines for mobile app development and of specific guidelines for privacy and usability sensitive apps is only superficially considered by most of the literature. The beforehand highlighted aspects of usability and information security¹⁹ are just two of multiple possible requirements. Current research seems not to state which specific requirements, if any, distinguish mHealth apps from other apps or which are needed to be more accented.

1.2 Objectives of this Thesis

The purpose of this thesis is to discover, identify and report issues and challenges of the development of mHealth apps by developing a mobile frontend for the ePill system (developed by the University of Cologne, <http://epill.uni-koeln.de>). ePill is a patient-centered health IT service which offers information on pharmaceuticals and aggregation of pharmaceutical data in context.

During the development of a mobile frontend for ePill, all requirements can be addressed

¹⁵ cf. Badashian et al. (2008) p. 108

¹⁶ for humans visible controls and layout of an application

¹⁷ cf. Directive 95/46 of the European Parliament and of the Council (October, 24th 1995), Directive 2002/58 of the European Parliament and of the Council (July, 12th 2002) cited by Future of Privacy Forum, Center for Democracy & Technology (2011), p. 16

¹⁸ cf. Njie (2013), p. 20

¹⁹ information security stands for prevention from unauthorized access, modification, use or disruption of information and information systems

more easily than in a completely theoretical context. As a side effect, a mobile app for ePill will increase the accessibility for the ePill system in general, and thereby increase the possible user value. In critical situations in which one does not have a desktop computer at hand, a mobile easy-to-use app can be of value.

The experiences gained during the development refer to general mobile app development, but also to the specific development of mHealth apps.

Mainly this thesis aims to describe the planning and the development process and discuss all discovered issues and challenges for planning and developing mHealth apps. One sub-objective is to give a short overview about the state of research on guidelines and important factors of mHealth app development. **TODO: LIST SUBAIMS**

2. The ePill System

2.1 The System in General

The ePill system (<http://epill.uni-koeln.de>) was developed by the University of Cologne to improve the readability and comprehensibility of instruction leaflets contained within the packaging of pharmaceutical drugs. Additionally ePill aims to provide further information on adverse reactions and interactions of different medical drugs. ePill emphasizes an easy readability and access to informations.

ePill is currently a prototype of the planned system, used only for research purposes and it is only actively used by the University of Cologne. Therefore it is only localized in German and contains just pharmaceuticals available in Germany. ePill utilizes the "GELBE LISTE PHARMINDEX"²⁰, provided by Medizinische Medien Informations GmbH MMI as main source for pharmaceutical information.

The system provides three major functions: searching for pharmaceuticals, display information on pharmaceuticals and supplementing services.²¹ The search enables the user to find corresponding pharmaceuticals depending on specified parameters in the underlying database. As an extend, the display functionality enables the user to read the leaflet information in an optimized fashion. Finally supplementing services are provided to refine the displayed information (e.g. select the level of detail of the displayed information), linking pharmaceuticals as well as other information and aggregate pharmaceutical information (e.g. interactions). **TODO: REFINE!**

An integration and personalization depending on the current user's health records was not implemented due to the arising privacy and trust challenges.^{22, 23} Instead the system was focused on patient friendliness regarding readability and comprehensibility.²⁴

²⁰ <http://www.gelbe-liste.de>

²¹ cf. for this paragraph Dehling, Sunyaev (2012a), p. 2 and Dehling, Sunyaev (2012b), p. 5

²² cf. Kaletsch, Sunyaev (2011) cited by Dehling, Sunyaev (2012a), p. 2

²³ cf. Kaletsch, Sunyaev (2011), pp. 5-6

²⁴ cf. Dehling, Sunyaev (2012b), p. 2

The system uses a Model-View-Controller (MVC) architecture²⁵ and utilizes a relational database as persistent data storage.²⁶ The data is organized with the pharmaceutical ingredients in mind. Products are any pharmaceuticals, which may contain specific molecules, which themselves may be related to specific adverse reactions with other molecules.

With this atomized organization of the pharmaceutical information, it becomes more easier to compare different pharmaceuticals and have very consistent information about molecules and adverse reactions with other pharmaceuticals.

2.2 The Web Application

The web application of the ePill system introduces itself highly customizable to the user. It offers the user to choose between a default view, a customizable view and an expert view. The default view aims to provide all necessary information in a compact way. The customizable view offers more choices for the controls and user interface elements to be displayed. The expert view activates the most detailed information level. The pharmaceutical informations to be displayed can be fine tuned for every view. ePill offers four different presets varying from only the most basic up to all available information. These presets can be further customized by afterwards selecting or deselecting items. ePill offers customization for the displayed leaflet information as well as the visibility of controls for access to supplementing services and settings in the sidebar. Additionally the font-size can be set to normal, bigger and biggest to support visually impaired users.

Three columns shape the layout. The first, leftmost column contains the main navigation for searching, pharmaceutical listings, basic functionality such as help pages and settings as well as extended functionality such as interactions research and adverse reaction lookup or pharmaceutical comparisons. The second, centered column contains the current content. This column has tabs²⁷, which can be assigned different contents. With this tabular layout, e.g. multiple, different search queries can easily be switched and held in parallel. The third, rightmost column can be used to dynamically display or hide se-

²⁵ cf. Dehling, Sunyaev (2012a), p. 3

²⁶ cf. Dehling, Sunyaev (2012a), p. 5 for this and the following two sentences

²⁷ user interface elements which imitate the look and functionality of card tabs inserted in paper files

lected information. Depending on the beforehand selected view, the left or right columns are hidden or visible. On the pharmaceutical detail page, the website offers the user the functionality to explain any term as well as a shortcut to the page's top.

The specific content layout is very consistent. Headlines are made salient and the arrangement of common sections are congruent. Changes in settings are applied with no delay and without a page reload.

Although this web application is not optimized for mobile applications and designed with a desktop computer in mind, it can be accessed by nearly any modern mobile computing device, such as a smart phone or a tablet, and can therefore categorized as a mHealth application. This categorization is important to the following section, to clarify the differences between the web application and the mobile client.

3. What is mHealth?

3.1 Definition

eHealth is defined as "a paradigm involving the concepts of health, technology, and commerce, with commerce and technology as tools in the service of health"²⁸.

Telehealth stands for the delivery of medical- or health-related information or services via telecommunication technologies.

mHealth in detail was defined as "medical and public health practice supported by mobile devices: such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices"²⁹. The introduction of smart phones such as the Apple iPhone and Android devices led to a greater audience and the evolution of mobile tablets further increasing the audience for mHealth purposes. A study relied on the Health Education Curriculum Analysis Tool (HECAT)³⁰ to group different mHealth apps together.³¹ HECAT content areas are describing eHealth application content areas, not only content areas for mHealth apps. The study by West et al. (2012) illustrates the distribution of apps in the HECAT content categories listed in Tab. 3-1.³² As Tab. 3-1 illustrates most of the available apps in 2011 in the Apple App Store in the United States of America belonged to the Physical Activity area, whereas drug-related and safety-related apps (like ePill) are the least two categories in terms of magnitude.

From February to May of 2012, a study by d'Heureuse et al. (2012) found several ten thousands of apps in the Google Play Store as well as the Apple App Store limited to the "Health" categories.³³ The study by d'Heureuse et al. (2012) shows the potential of mHealth for a broader healthcare supported by mobile devices. From March to May of 2012, the total number of apps increased by an average of 6.4% (Google Play Store) and

4.5% (Apple App Store) per month.³⁴

HECAT content area	n	%³⁵
Physical Activity	1108	33.21
Personal health and wellness	962	28.84
Healthy eating	651	19.51
Mental and emotional health	414	12.41
Sexual and reproductive health	243	7.28
Alcohol, tobacco, and other drugs	131	3.93
Violence prevention and safety	96	2.88

Tab. 3-1: Distribution of Apps related to their HECAT Content Area (N = 3336)³⁶

3.2 mHealth App Categories

Although Tab. 3-1 lists categories for mHealth apps, it focusses on content and less on the specifics for mHealth apps on other possibly important topics, such as information security or usability. Those content areas range from physical activity to health and wellness (mental, emotional, sexual or diet related) as well as for drugs and prevention. Other literature focusses on data practices and privacy risks with a more technical aspect³⁷.

Njie (2013) concludes that most of the mHealth apps deal in any way directly or indirectly (e.g. via usage behavior) with sensitive information.³⁸ Therefore ten levels of privacy risks were developed and a sample of 43 mHealth and fitness apps were assigned to the different levels. Tab. 3-2 illustrates the characteristics of every level as well as the distribution of the 43 analyzed apps.

The risk levels are based on the one hand on the information available to the app and on the other hand on security precautions implemented by the developer to prevent unau-

³⁴ cf. d'Heureuse et al. (2012), p. 20

³⁵ Apps could be assigned to multiple categories

³⁶ cf. West et al. (2012), p. 6, Table 2

³⁷ cf. Njie (2013), pp. 13-14

³⁸ cf. for this and the following paragraph Njie (2013), pp. 13-14, 19, 21

thorized access to this information. An important differentiation is also in the anonymity or identifiability of the information accessible by third parties, such as other apps, other developers or unauthorized individuals. The higher the accessibility, the identifiability or the possible harm done by this information, the higher the risk level to be assigned.

Level	Risk	Characteristics	% ³⁹
9	Highest	address, financial information, full name, sensitive or embarrassing health (or health-related) information, information that a malicious actor could use to steal or otherwise cause a user to lose money	40
8	High	geo-location	
7	Medium-high	DOB, ZIP code, any kind of personal medical information	
6	Medium	risk evaluated to be between level 5 and level 7	32
5	Medium	email, first name, friends, interests, weight, information that is potentially embarrassing or could be used against a person (e.g., in employment)	
4	Medium	risk evaluated to be between level 5 and level 3	
3	Medium-low	anonymized (not personally identifiable) tracking (e.g., app usage), device info, a third party knows the user is using a mobile medical app	28
2	Low	risk evaluated to be between level 3 and level 1	
1	Low	any kind of anonymized data that does not include medical health-related data or personally identifiable information	
0	No		0

Tab. 3-2: Privacy Risk Levels of mHealth Apps (N = 43)⁴⁰

As stated by Istepanian, Jovanov, Zhang (2004), another categorization is possible. They categorized mHealth applications into administrative connectivity, financial connectivity or medical connectivity.⁴¹ Because of the lack of smart phones and a far lesser availability of mobile devices in 2004 compared to today, this article cannot take the recent

³⁹ of apps in the sample

⁴⁰ cf. Njie (2013), p. 13

⁴¹ cf. Istepanian, Jovanov, Zhang (2004), p. 409

development in mobile devices into account. The administrative connectivity handles appointments, electronic patient records and any non-financial transactions.⁴² The financial connectivity includes all financial transactions such as purchases, billing or any financial services. The third connectivity, the medical connectivity, stands for mobile monitoring and diagnostics.

As described, there are three different categorization approaches for mHealth applications: The content, the information security risk-level and the overall connectivity function. For the content-category as well as the connectivity-category, multiple assignments are possible. Combined these categorization approaches form a specific grouping of mHealth apps. Depending on the categorization in the privacy risk, one can take precautionary measures. With the categorization in a HECAT content area one can identify the target audience more precisely as well as with the help of the connectivity category.

3.3 Classification of the ePill Web Application

ePill can be categorized in the HECAT content areas as "Alcohol, tobacco, and other drugs", because it informs about (medical) drugs. Since ePill also informs about adverse effects and interactions between pharmaceuticals, it belongs furthermore to the content area "Violence prevention and safety".

The ePill web application is not connected to any electronic patient records, nor does it store any user related information such as a history of the last searched pharmaceuticals, but it does not utilize SSL-encryption. Therefore it might not be collecting information or storing anything, but third parties could collect user specific information by monitoring. Putting this information into context with the risk levels developed by Njie (2013), if SSL-encryption would be utilized by the ePill web application, it could be categorized as level three. With SSL-encryption, third parties could still retrieve browser and OS specific information, but not the data sent and retrieved with each request such as pharmaceutical information. Without encryption all data sent and retrieved is visible to possible eavesdropper. With information about searched pharmaceuticals, one could assemble an overall

⁴² cf. for this and the two following sentences Istepanian, Jovanov, Zhang (2004), p. 409

picture of the ingested medications and therefore extrapolate possible diseases. Still, all data is anonymized.

Having in mind, that ePill still is in early prototyping and assuming, that the SSL-encryption will be an upcoming feature, the risk is more of a medium to low level. Dealing with anonymous data only and protecting them with encryption leaves very little room for serious risks. We would therefore categorize ePill as a level two in terms of privacy risk levels.

Although ePill does not absolutely fit in any of the connectivity categories, its closest fit is within medical connectivity. Because of the aim to provide pharmaceutical (therefore medical) information, it could still be found within the medical connectivity category.

Concluding this categorization, we would suggest to categorize the ePill web application as a low privacy risk, drug and safety-related medical connectivity mHealth application.

3.4 Why is a special Focus on mHealth Apps warranted?

mHealth apps differ in some way from general (mobile) applications but also from eHealth applications. While mHealth apps can be used in many different situations and with very different intentions, the special focus on e.g. equality of all users and accessibility for all possible users is important for mHealth apps. This is supported by the definition of mHealth apps: "mHealth apps aim at providing seamless, global access to tailored health IT services and have the potential to alleviate global health burdens"⁴³, which means that they should be accessible by mostly all possible users. Whereas other types of apps do not necessarily need to be accessible by any user, we want to stress that accessibility does not only mean usability (especially for elderly people), but also global for different social layers or cultures⁴⁴.

mHealth apps deal with medical- or health-related information and have therefore to deal with sensitive information and have to address privacy risks and concerns. As pointed

⁴³ Dehling, Sunyaev (2013), p. 1

⁴⁴ cf. Dehling, Sunyaev (2013), p. 1

out by Njie (2013) and already referred to in Tab. 3-2, many mHealth apps deal with highly sensitive data and have serious privacy risks. Dehling, Sunyaev (2013) illustrates the possible damages through leaks, manipulation or loss of information, such as loss of affection and reputation or lessened employment possibilities.⁴⁵

⁴⁵ cf. Dehling, Sunyaev (2013), p. 7

4. The Development of the Mobile Client

4.1 Preconditions

4.1.1 Norms for Mobile Apps

Because ePill is currently used in Germany only, we will focus on laws applicable in Germany. These laws are namely the Telekommunikationsgesetz, the Telemediengesetz, the Directive 95/46/EG as well as the data protection act of North Rhine-Westphalia. The Telekommunikationsgesetz and Telemediengesetz are laws by state, whereas Directive 95/46/EG is an European directive, specified by the respective Member States.

German federal states have their own data protection acts. In this thesis we will focus on the data protection act of North Rhine-Westphalia as ePill is located in North Rhine-Westphalia.

As the topmost layer of laws, the Directive 95/46/EG defines more general directives. Article 4 defines national law applicable, if the natural or legal person, the controller⁴⁶, is located on a Member State's territory⁴⁷ or if any of the processing takes place on a Member State's territory⁴⁸. It is required, that the controller asks the user to consent to the use and collection of data⁴⁹. Explicitly, "data concerning health and sex life"⁵⁰ shall not be processed, only if the user consent explicitly⁵¹, or if the processing is done by a healthcare professional under national law and for preventive medicine, medical diagnosis or treatment or for the management of health-care services⁵².

This is refined by the Telemediengesetz. § 13 section (1) states, that the controller has to inform the user in a commonly understandable manner about the data which is col-

⁴⁶ cf. The European Parliament and the Council of the European Union (1995), Article 2, (d)

⁴⁷ cf. The European Parliament and the Council of the European Union (1995), Article 4, 1., (a) and (b)

⁴⁸ cf. The European Parliament and the Council of the European Union (1995), Article 4, 1., (c)

⁴⁹ cf. The European Parliament and the Council of the European Union (1995), Article 7, (a)

⁵⁰ The European Parliament and the Council of the European Union (1995), Article 8, 1.

⁵¹ cf. The European Parliament and the Council of the European Union (1995), Article 8, 2., (a)

⁵² cf. The European Parliament and the Council of the European Union (1995), Article 8, 3.

lected and the form of processing of this data⁵³. For a legal consent, the controller has to ensure, that the user is aware of his consent, that the consent is minuted, that the content of the consent is always available to the user and that the user can revoke his consent⁵⁴. The same laws are stated in §§ 91, 93 and 94 of the Telekommunikationsgesetz⁵⁵. Also the data protection act of North Rhine-Westphalia constitutes the same laws⁵⁶ with the only restrictions, that its scope is limited to North Rhine-Westphalia.

Therefore ePill should explicitly inform the user that no data is stored and only anonymized transacted to find matching results, to comply with the stated laws.

4.1.2 Best Practices

The World Wide Web Consortium (W3C) has published a document in 2008 which states the basic best practices for developing for the mobile web. This document states 60 best practices, which shall ensure a minimum quality level for mobile web applications. These best practices emphasize the need of regard of the device's capabilities and supported technologies⁵⁷.

The document focuses on mobile web development⁵⁸, which has differences to native app development (e.g. the usage of frames and the accessibility of the device's specific features). Most of the best practices are applicable in both development environments.

For the mobile frontend of ePill, we can focus on best practices related to the user interface, input and navigation methods as well as general best practices, because it does not need more specific device capabilities, such as positioning and navigation features. Depending on the framework chosen, some of the best practices are already implemented by the framework. I.e. a thematic consistency⁵⁹ is by default provided by frameworks

⁵³ cf. Bundesregierung der Bundesrepublik Deutschland (2007), § 13, section (1)

⁵⁴ cf. Bundesregierung der Bundesrepublik Deutschland (2007), § 13, section (2)

⁵⁵ cf. Bundesregierung der Bundesrepublik Deutschland (1996), Section 2, §§ 91, 93, 94

⁵⁶ cf. Der Innenminister des Landes Nordrhein-Westfalen (2000), Section 1, §§ 2, 4, 5

⁵⁷ cf. World Wide Web Consortium (2008), e.g. 2., 11., 21., 42.

⁵⁸ cf. World Wide Web Consortium (2008), Abstract

⁵⁹ cf. World Wide Web Consortium (2008), 1.

such as TouchKit for Vaadin. Although they can be overridden, a consistent theme is provided. Wessels, Purvis, Rahman (2011) support the importance of a consistent appearance, cross platform and for both the mobile as well as the desktop application, if existent⁶⁰. Lica (2010) limits this to specific elements and points out, that mobile apps should provide just enough functionality to be useful and should not replicate the desktop optimized website.⁶¹

Other best practices such as utilizing a navigation bar at the page's top⁶² for the main navigation are already adapted by different platforms and frameworks, such as Vaadin with TouchKit⁶³, iOS⁶⁴ and Android⁶⁵.

Best practices which are mainly determined by implementations of the developer, such as the usage of colors⁶⁶ or the chosen input methods⁶⁷ are often supported by the different platforms or frameworks but cannot be guaranteed by those. Even if different input methods such as a number pad for numeric inputs are provided by the framework or platform they still need to be adapted and utilized by the developer to act in line with the best practices.

The World Wide Web Consortium (2008) furthermore specifies a "Default Delivery Context"⁶⁸, which defines the minimal capabilities for mobile devices which should be supported. Tab. 4-1 illustrates the minimal capabilities suggested by W3C.

Nowadays it will be hard to match all of the requirements. E.g. a total maximum page weight of 20 kilobytes corresponds to the average file size of a 200 by 120 pixel JPEG-

Parameter	Value
Usable Screen Width	120px
Markup Language Support	XHTML Basic 1.1 delivered with content type application/xhtml+xml.
Character Encoding	UTF-8
Image Format Support	JPEG. GIF 89a.
Maximum Total Page Weight	20 kilobytes.
Colors	256 Colors, minimum.
Style Sheet Support	CSS Level 1. In addition, CSS Level 2 @media rule together with the handheld and all media types.
HTTP	HTTP/1.0 or more recent.
Script	No support for client side scripting.

Tab. 4-1: Default Delivery Context for Mobile Optimized Applications⁷¹

compressed file is about 10 kilobytes⁶⁹ and two images would already exceed the maximum page weight. With mobile devices such as a Samsung Galaxy S3, which has a minimum of 720 pixel wide display, 120 pixels are far too less, even as a minimum width. Also nearly any mobile browser supports client side scripting (e.g. JavaScript). For more detail, <http://caniuse.com> holds compatibility charts of different browser features for nearly any browser available. The parsing of JavaScript Object Notation (JSON) for example is supported by 93.41% of all mobile browsers according to caniuse⁷⁰.

Nevertheless, minimizing the total page size is still a concern. Wessels, Purvis, Rahman (2011) points out, that smaller pages lead to faster load times and therefore provide a more efficient experience for the user.⁷² Nicolaou (2013) suggests different approaches to reduce page size as well as load time: Scripts and markup should be minified⁷³ and

⁶⁹ Tested with 60% compression rate and a random photograph

⁷⁰ cf. http://caniuse.com/#cats=JS_API, JSON parsing

⁷¹ cf. World Wide Web Consortium (2008), 3.7 Default Delivery Context

⁷² cf. Wessels, Purvis, Rahman (2011), p. 1066

⁷³ cf. Nicolaou (2013), p. 49

included inline⁷⁴ where it is possible. Preloading components and reducing DNS lookups can also result in a faster user experience.⁷⁵

Generally, Nicolaou (2013) recommend using a Content Delivery System (CDN), placing style sheets at the top of the source code, scripts at the bottom and using resized images rather than scaling them via HTML or CSS⁷⁶.

A study by Dahanayake et al. (2010) came to the result, that 71% of all responding web developers knew about the best practices, but only 11% said, that they would understand these, 56% have a vague understanding and 33% do not understand the best practices.⁷⁷

Ayob, Nurul Zakiah binti, Hussin, Ab Razak Che, Dahlan (2009) adjusted and combined four different guidelines for application development, namely Shneiderman's Golden Rules of Interface Design, Seven Usability Guideline for Mobile Device (Abid Warsi, 2007), Human-Centred Design (ISO Standard 13407) and Mobile Web Best Practices 1.0 (W3C). Out of these guidelines, they developed the Three Layers Design Guideline for Mobile Application⁷⁸. This guideline consists of three phases, which themselves represent different contexts, namely analysis (and the context of use), design (the context of medium) and testing (the context of evaluation). Tab. 4-2 illustrates this guideline.

This thesis will follow the Three Layers Design Guideline, as it is the latest guideline and includes parameters set in a multitude of other guidelines. The third phase will be shortened due to the temporal restrictions of this thesis. The exact process will be outlined in the following subsections.

Tab. 4-2: Three Layers Design Guideline for Mobile Application⁷⁹

4.1.3 Internal Requirements

While developing a mobile frontend for ePill, it was important to us, that the main functionality of the web client will be optimized but not reduced in its main functionality. Therefore a good user interface is indispensable. All functionality should be accessible easily and without confusion for the user. Interactive elements such as buttons should be visible salient and have an immediate response to reduce the user's uncertainty **TODO: CITE?**. The general design, the color scheme and the fonts should be used in line with the web application to improve the recognition value. **TODO: CITE?**

Another top priority is the accessibility of the app for as many users as possible. Therefore it is necessary to provide a cross-platform app that is accessible by as many mobile platforms as possible and to have an intuitive user interface which also enables elderly people to use it efficiently.

Modularity and flexibility is another important factor. ePill is designed to be flexible and scalable and the mobile client should incorporate the same idea. A scanning of barcodes on the packaging of pharmaceuticals could be implemented on a later stage to even further ease the use and increase the effectiveness.

4.2 Analysis

4.2.1 Assignment of a mHealth App Category

The mobile app does not differ from the web application in terms of privacy risks, content or connectivity. The mobile app aims to provide the same main functionality as the web application optimized for mobile devices, therefore it also belongs to the same connectivity category, the medical connectivity, as the web application. Also no data is stored on the device and no additional usage data is sent to the server.

We plan to implement a SSL-encrypted connection to the server as soon as the later mentioned is capable of accepting and responding via SSL-encryption.

We would suggest to categorize the ePill mobile application as a low privacy risk, drug- and safety-related medical connectivity mHealth application and it should be categorized the same as the web application.

Possible future features might change the classification (e.g. the addressed barcode scanning) if data handling or storage is altered and with it other privacy risks may arise.

4.2.2 The Different Operation Systems

4.2.2.1 Android

Android is a mobile OS developed by the Open Handset Alliance⁸⁰, with Google being

⁸⁰ <http://www.openhandsetalliance.com>, last visited on 09/02/2013

one of the biggest members. It is Linux based and was unveiled in 2007. Android is released by Google under the Apache License and is therefore Open Source.⁸¹ Developing for Android requires the Android SDK (or NDK) to be installed on the development computer. Developing apps with the SDK is done by writing Java code and defining the layout in specific XML⁸². Android apps are executed in the Dalvik managed runtime⁸³ by default, except if they utilize the NDK. With the NDK apps can be (partly) written in C or C++ and are executed outside the Dalvik runtime which can be helpful for reusing existing code or executing CPU-intensive operations.⁸⁴

While Android is adapted by many manufacturers as well as consumers, a software-based and a hardware-based fragmentation is visible.⁸⁵ Fragmentation means in this case a variety of different software and hardware which is at least partly incompatible. This fragmentation offers the user the choice to find exactly what he is looking for and enables more personalization. However, fragmentation may lead to non-consistent applications on different devices as well as delays in updates. According to Google, an Android version released 2010 (2.3 "Gingerbread") still has a distribution of around 30.7%.⁸⁶ This also implies that developers do not only have to regard latest versions of the OS, but also older versions. This means in return, that developers cannot always take full advantages of new capabilities as well as they need to pay much more attention to backwards compatibility.

For Android multiple IDEs are available. Eclipse⁸⁷ is a popular IDE and is officially supported by the Android SDK.⁸⁸ Android Studio, an Android optimized version of IntelliJ IDEA⁸⁹, is still in development but already a stable IDE and greatly supported by

Google⁹⁰.

Apps can be distributed directly to single phones or via an app store, e.g. the Google Play Store⁹¹. The Google Play Store has guidelines, which must be followed⁹², but no review process, in which compliance with the guidelines is verified, is performed.⁹³

4.2.2.2 iOS

iOS is the proprietary OS developed by Apple for mobile devices. It was first introduced in 2008. In contrast to the Android OS only Apple develops hardware and software that runs the iOS operation system. According to Apple, 94% of all active iOS devices run the latest version of iOS 6.⁹⁴ Compared to Android, all versions of iOS released before 2011 have a cumulative distribution of only 1%. Hardware-based fragmentation on iOS is mainly based on the screen size: Two different for the phones and one for the tablets.

iOS apps can only be developed in Xcode⁹⁵, which is only available for Apple Mac. Xcode combines user interface design and coding. Coding is mainly done by writing Objective-C code but also supports native code written in C or C++. Designing interfaces is done with an Interface Builder called user interface integrated into Xcode.⁹⁶

In contrast to Android, iOS apps can only be published via the Apple App Store⁹⁷, or on registered devices with a special license by Apple⁹⁸. For submitting apps to the Apple

App Store, one must obtain a developer license by Apple⁹⁹. After submitting, all apps are reviewed and compared to Apple's guidelines¹⁰⁰.

4.2.2.3 Windows Phone 7 and 8

Windows Phone 7 was released in 2010 as the successor of Windows Mobile. Windows Phone 8, the phone version of Windows 8, were released in 2012. Both utilize the "Metro" design, a tile-based design.

Development for Windows Phone requires the Visual Studio IDE.¹⁰¹ Visual Studio is only available for Windows. C# or Visual Basic are the main programming languages and XAML is used for user interface design¹⁰². C++ can be utilized for graphic intensive applications.

The Windows Phone Store¹⁰³ is a closed store like the Apple App Store. This means, that an enrollment is needed to publish apps and the release of an app is preceded by a review process.¹⁰⁴ Unlike the other stores, the Windows Phone Store offers the possibility to try apps out with reduced functionality.

4.2.2.4 other

Depending on the source of statistics, the lead market share is held by different OS. Nevertheless other OS, e.g. Symbian, which was an important OS in 2008 with 47% market share of smartphone OS¹⁰⁵, is nowadays not listed at all or with less than 10% market

⁹⁹ cf. <https://developer.apple.com/programs/ios/>, last visited 09/11/2013

share^{106, 107, 108}.

We will not take these OS into account, whose combined marketshare is around only 10%, as this would exceed the time frame allocated for this thesis.

4.2.3 Possible Frameworks and Technologies

4.2.3.1 Completely native

Building native apps for supporting Android, iOS and Windows Phone, means maintaining three different projects in three different programming languages and three different user interface definitions. But native apps offer the most seamless user interface integration into the OS and the best performance. **TODO: ALSO DIESEM UMSTAND UND DER AUSFÜHRUNG WAS NATIVE IST UND WARUM WÜRD ICH MEHR SÄTZE SCHENKEN!**

While the seamless user interface integration could help people using the app in a familiar context, performance is not an issue for the ePill project. The costs for learning the specific aspects of those frameworks, developing and maintaining the three implementations are not reasonable for the given time frame of this thesis.

Additionally, we do not have an existing web service which the app could utilize to receive data from the server. With the logic already implemented, the currently used framework Vaadin does not offer a way to provide a web service. This additional effort is definitely a decisive argument.

4.2.3.2 HTML 5, jQuery mobile and Phone Gap

Providing an app for nearly any mobile device is possible with a web app. Based on web technologies like HTML, CSS and JavaScript, apps can be brought to nearly any mobile OS with only one implementation. Unsupported features or OS can be found on Phone-

¹⁰⁶ http://gs.statcounter.com/#mobile_os-ww-yearly-2008-2013

Gap's feature page¹⁰⁹.

As HTML5¹¹⁰ and JavaScript is supported by most mobil devices, frameworks like jQuery mobile¹¹¹ provide a common looking user interface without much additional effort. PhoneGap¹¹² enables web-based apps to access the device's capabilities like the camera or local storage¹¹³.

Still, with this approach we would need a web service, which would be consumed with jQuery. The web app approach lessens the effort by developing multiple apps with only one code basis and user interface definition but still has the time consuming need for a new web service.

4.2.3.3 Xamarin

Xamarin¹¹⁴, also known as MonoTouch, is an IDE and framework, which produces native apps for Android, iOS and Windows Phone from just a single C# code basis. Different user interface definitions are still needed, but it combines the advantages of native apps and web apps.

Xamarin used with Visual Studio or Xamarin Studio, while Visual Studio is only available for Windows, Xamarin Studio is available for both Windows and Mac OS X.

Also apps developed with Xamarin would need an additional web service, which cannot be provided in the given time. Additionally, Xamarin is only free by meeting specific requirements, so it is likely to be more expensive than providing a web app.

4.2.3.4 Vaadin and TouchKit

Vaadin¹¹⁵ is a Java framework, with which the developer only needs to write application

¹⁰⁹ <http://phonegap.com/about/feature/>

¹¹⁰ <http://www.w3.org/TR/2012/WD-html51-20121217/>

¹¹¹ <http://jquerymobile.com>

¹¹³ for a detailed overview: <http://phonegap.com/about/feature/>

¹¹⁴ <http://xamarin.com>

¹¹⁵ <https://vaadin.com>

code and define a user interface included in the Java code. The framework builds the user interface as HTML and handles all communication between the client and the server. TouchKit¹¹⁶ enables a Vaadin project to easily add a mobile web client. It provides various user interface controls which were optimized for mobile devices. It also provides access to the device's capabilities, such as positioning, offline storage or camera.

TouchKit supports iOS 5 or newer, Android 2.3 or newer and Windows Phone 8. Vaadin as well as its add-on TouchKit, is focused on WebKit¹¹⁷-based browsers¹¹⁸, although it is compatible to most of the mobile browsers. Nevertheless, browsers which are not based on WebKit might be completely unusable or might have layout defects.

TODO: KRISTY'S REMARK Using Vaadin and TouchKit for ePill has the advantage, that we would not need an additional web service, we could use the existing code and just add a TouchKit-based user interface, which seamlessly adapts to the existing code.

4.2.4 The Choice for Vaadin and TouchKit

Finally we chose Vaadin and the TouchKit add-on as the framework for the mobile frontend. The main reason to this is the lack of an accessible web service in Vaadin itself. Without a web service, we would have had to build a web service first to access the data layer or the application's logic.

Furthermore we wanted the complete system to be as homogenous as possible. Utilizing the TouchKit Add-On for Vaadin, we reused as much existing code as possible and infrastructure by only adding another layer. This results in a much improved maintainability as the coding style is the same for the web application and the mobile application. Additionally no additional IDEs or frameworks need to be included or maintained.

The missing compatibility to not WebKit-based browsers as well as the abstracted user interface definition might be drawbacks. With a less abstract user interface definition we

¹¹⁶ <https://vaadin.com/touchkit>

¹¹⁷ <http://webkit.org>

¹¹⁸ cf. <https://vaadin.com/book/-/page/mobile.considerations.html>, last visited 09/11/2013

would have more options to fine tune the resulting user interface.

4.3 The Planning Process

As already mentioned, the ePill system is already a functional prototype and the yet to develop mobile frontend is mostly an additional user-interface. Therefore no system-wide planning, including e.g. data organization, is needed but the data handling and user interfaces have to be planned.

Having the already existing application logic in mind, the planning of data handling is reduced to a functional planning **TODO: DEFINE**. To be able to have the functions available for the user, we have to combine the planning of the functional aspects with the user interface, therefore we will plan the user's flow through the application (user flow) which pays attention to the accessibility of the of the functions of the mobile web app in the right context **TODO: WHICH**, and combines functional and user interface planning. For the ease of explanation, we added some mockups and screenshots. We decided to show them uncolored to prevent distraction from highlighting colors and because the color scheme is not final yet. We decided to focus on smaller mobile devices such as phones and not on tablets, because smaller user interfaces can be expanded and are still usable. If the user interface is designed for a bigger screen and is presented on a smaller screen, either the elements become too small or the user needs to scroll through the interface. We will optimize the app's implementation for various layouts depending on the device's screen size at a later stage.

The three major functions of ePill (Search, Display and Supplementing Services) should be accessible as fast as possible. The display functionality and some supplementing services (e.g. the term explanation functionality) are only able to present results if a pharmaceutical is selected. So we designed Fig. 4-1 as a minimal starting screen with every main function quickly accessible. Due to some missing user interface controls provided by Vaadin TouchKit, such as the search bar, we finally implemented the start screen as illustrated in Fig. 4-2. This furthermore resulted in a more separated presentation of search string input view and result view, as presented in Fig. 4-3 and Fig. 4-4.

Fig. 4-1: Main Screen Mockup

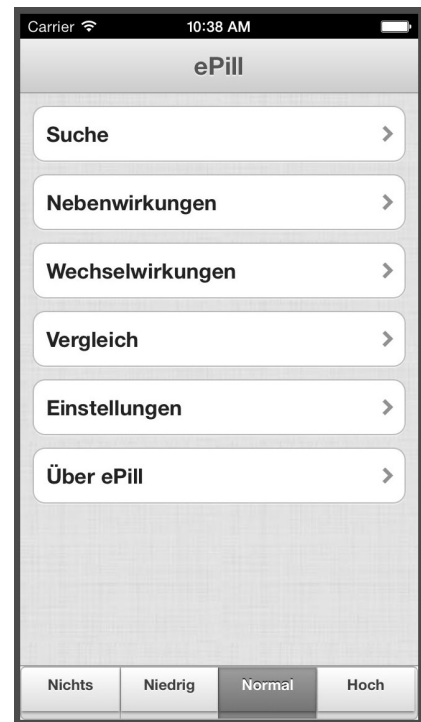

Fig. 4-2: Final Main Screen

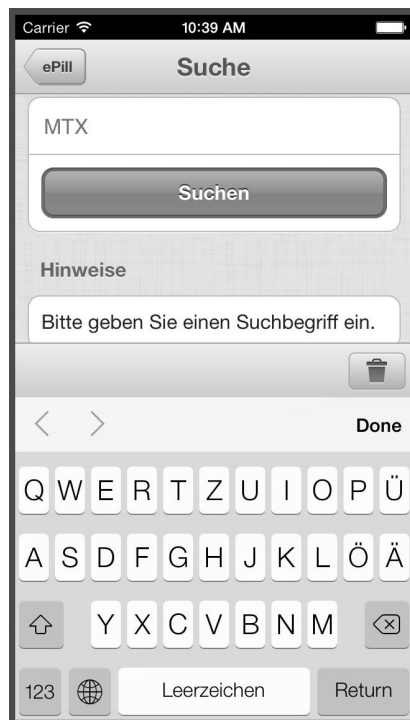

Fig. 4-3: Search Input Screen

Fig. 4-4: Search Result Screen

Throughout the planning and designing we tried to reproduce common patterns and user controls, and therefore we utilized the navigation back on the top left corner, which is illustrated by a leftwards oriented arrow-shaped button. Central navigation which specifies the view is centered in the main content area in the screen's center.

Most of the views offer a toolbar at the screen's bottom. This toolbar contains controls which are used for navigation inside the screen's center view, such as the ability to go back or to the top or to navigate to a specific header. In the pharmaceutical details view with much information visible, it can be very handy to jump right to the header one is interested in. Additionally, some controls are added in the toolbar which enable further interaction with the information displayed, e.g. adding the currently visible pharmaceutical to the comparison list, which I will discuss later.

The web application has rich customization possibilities. One can adjust the font size, the details of pharmaceuticals to be displayed and the layout of the web application itself. As it turned out, it is not applicable for the user to change the mobile apps layout, because the user interface is so too compact to add additional elements and too few elements are visible to deem it necessary to hide any given element.

The comparison list is a concept added to the mobile application and derived from a screen in the web application. The web application offers a view in which pharmaceuticals can be added and afterwards, via a button click. Aggregated information such as adverse reactions can also be listed. Because we have much less available screen space in the mobile app, we decided to have the list globally available throughout the entire app. For example, if one searched for a pharmaceutical and has selected one to display detailed information, he can easily add this pharmaceutical (via a button in the toolbar) to his comparison list. If one now selects the side effects functionality in the main screen, he sees his comparison list and can add more to it. This screen is illustrated in Fig. 4-7. If one decides to do so, he is presented a search input screen but can in the search result screen only tick on those pharmaceuticals he wants to add to his comparison list and not see the pharmaceutical details on click. This is illustrated in Fig. 4-8.

Fig. 4-7 also highlights the toolbar. The leftmost button scrolls back to the top, whereas on the right side we have an add button which brings up the already discussed search view and the trash button, which clears the comparison list.

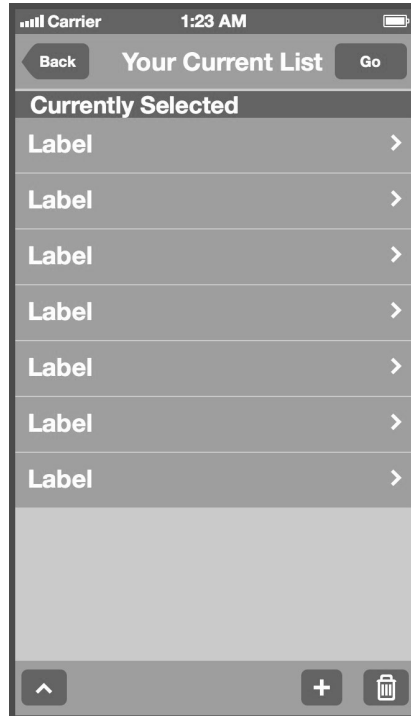

Fig. 4-5: Comparison List Mockup

Fig. 4-6: Results Screen Mockup

Fig. 4-7: Comparison List Screen

Fig. 4-8: Results Screen

Fig. 4-9: Confirm Dialog Mockup

Fig. 4-10: Details Screen Mockup

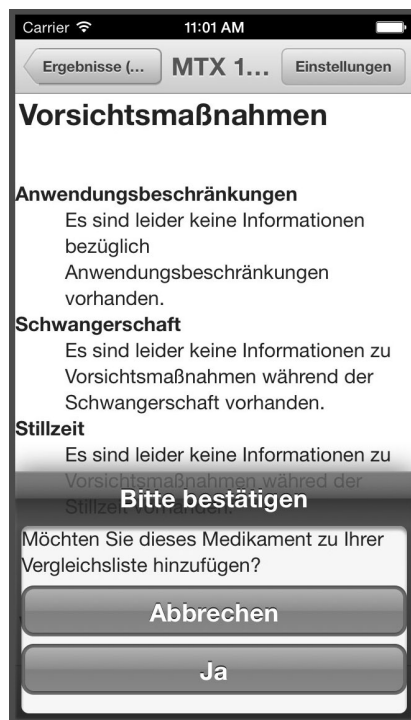

Fig. 4-11: Confirm Dialog

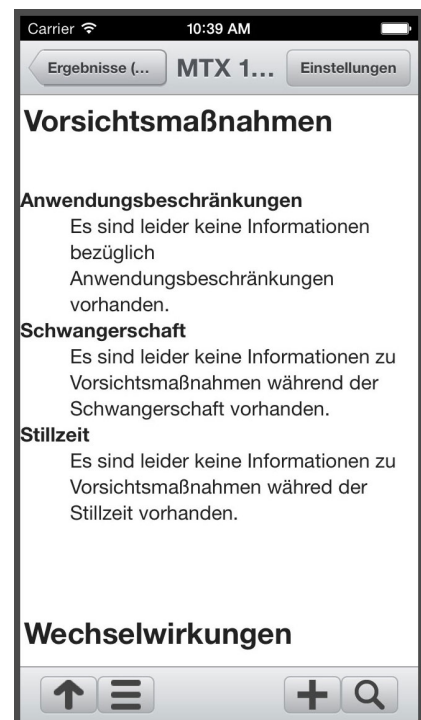

Fig. 4-12: Details Screen

The button on the top right corner labeled "Go" starts the currently selected function, e.g. adverse reactions on the comparison list.

To prevent users from faulty operations, we will add dialogs asking to confirm the chosen operation where adequate. This currently only fits to the delete and add operations of the comparison list, as illustrated in Fig. 4-11.

Fig. 4-12 illustrates the pharmaceuticals details screen. This screen presents all information for a specific pharmaceutical, e.g. after the selection of one pharmaceutical in the search results screen or from the comparison list as illustrated in Fig. 4-7. Basically, this screen consists of the back navigation button in the top left corner, the toolbar in the bottom and the centered main content area as most of the mobile app's screens. While the main content area displays the leaflet information segmented and only the chosen information, the toolbar offers different operations. On the lower right corner, the add button allows the user to add this specific pharmaceutical to his comparison list. The left side of the toolbar offers a back to top button just such as the comparison list screen as well as a navigation button, enabling the user to jump to any of the sections by which the main content is segmented. A click on this button reveals a list of the sections through which the user can scroll and select one to jump to. Another click on this button closes the list as well as the section selection.

4.4 The Implementation Process

The implementation of the planned user flow was struggling at the beginning because of some differences of Vaadin and TouchKit to other frameworks we worked with beforehand. For instance, TouchKit does not provide a search bar which can be attached to the navigation bar as planned in the mockups, furthermore the ePill web application is currently based in Vaadin 6, whereas TouchKit 3 is based on Vaadin 7. We tried to utilize Vaadin 6 and TouchKit 2 for the mobile app but as it turned out, TouchKit 2 has many drawbacks in comparison to TouchKit 3, such as far less documentation, tutorials and example projects. The choice for Vaadin 7 and TouchKit 3 resulted in, that we could not just include the ePill web application and directly access the business logic, as some adjustments were needed to upgrade a Vaadin 6 project.

Because time was still a factor to us, we decided to include as much as possible from the web application and copy and modify as little as possible. During further development, when the web application is upgraded to Vaadin 7, both projects can be merged together and code redundancies can be removed. The choice for Vaadin 7 brought some additional

work for us as we had to adjust references to e.g. the main window and application because their handling did change.

After having set the stage for the implementation, we discovered that Vaadin does not seem to have a community as big and as active as Node.js¹¹⁹ or django¹²⁰. While we made the experience that to most issues an answer can be found in the related forums, mailing lists or community pages as well as on more general websites such as Stack Overflow¹²¹, only very few answers and questions were found on Stack Overflow regarding Vaadin or TouchKit. A direct comparison between the official django mailing list¹²² and the Vaadin forum¹²³ revealed that while the django mailing list had 40,367 topics¹²⁴, the Vaadin forum had 14,523 threads¹²⁵, including news and forum guidelines. Nevertheless, the Vaadin forum was often helpful.

Programming with Vaadin is easy after the first steps into the framework were successful. The coding style supposed by the framework was consistent and helped achieving fast results. Nevertheless, missing controls are a drawback and the inflexibility of the framework is both an advantage and disadvantage.

The lack of components such as alert- and confirm-dialogs or search bars is compensable. During the development, we utilized popovers to imitate the well known appearance of dialogs in most of the mobile OS. Vaadin's popover component is functional, as it provides an overlay with a responsive layout for different screen sizes but is not completely customizable, e.g. the bar at the popover's top cannot be customized and buttons cannot be added to this bar. Vaadin's popover has also a much bigger border than we would have used with a common dialog component. This reduces the useable content area. Addition-

¹²⁴ last visited on 09/16/2013

¹²⁵ last visited on 09/16/2013

ally the borders distract the user and reduces the focus on the content and buttons.

We implemented a workaround for the missing search bar attached to the navigation bar by adding an additional view. As stated beforehand, we planned to attach the search bar directly beneath the navigation bar to enable the user to quickly access the search functionality. Results were planned to be displayed as an overlaid list. We had to abandon the idea of an overlaid list as well because the Vaadin TouchKit framework did not have the needed functionality at hand. Overlays looked either unfamiliar or complicated the use of the app, especially for dismissing the results. Finally we chose to display a view containing an input field, a button and a label displaying information like the minimum length of the query. The results are displayed in another standalone view as plain list.

Another issue we discovered was the drop for dynamic style sheets and themes in Vaadin 7. In Vaadin 6 one could swap the used theme during runtime, which was used to adjust the font size. In the time given we could not implement a workaround. We tried by adding CSS classes to the different controls but this either meant a high complexity for the algorithm to discover all controls nor a high need of memory if we were to keep references for the controls.

The Vaadin framework did help to get fast results. E.g. the settings screen for customizing the displayed leaflet information could be implemented in a short time thanks to the automatic handling of references between the client- and the server-side. Nevertheless it was not possible to receive specific events like a "will appear" or "did appear" for views. These events are needed for refreshing the view or specific controls if needed. Java and Vaadin offer listeners for "value changed" events but those still need a reference for the controls, which have to be passed along through the views. The main screen contains a toolbar at the screen's bottom to select a preset of visible information on leaflets. If now the user decides to change the preset in a lower view, this toolbar needs to be updated as well. Additionally to the increased reference count this method has the drawback that the toolbar gets updated on every value change, although it is not visible. With a "will appear" event the update would have been done only once directly before the toolbar becomes visible.

Much of the layout from the web application could be reused with only minor adjustments, thanks to Vaadin's seamless TouchKit integration. The comparison functionality is still an issue. Comparing two pharmaceuticals can only be effective, if related information is presented closely. During the development we experimented with a vertical instead a horizontal layout, meaning that each related information of the two pharmaceuticals are presented beneath each other, not side by side, but it became very confusing because of the doubled page length. For now we concluded that a horizontal layout and a landscape orientation will be best in this case.

4.5 Validation of the Mobile App

In this section we will compare the developed app to the norms and best practices highlighted in section 4.1 Preconditions, as well as to all requirements stated in section 4.2 Analysis.

Because no user-related data is stored, neither personal nor usage related, we do not have any conflicts with the norms mentioned in section 4.1.1 Norms for Mobile Apps.

As already stated, Vaadin and TouchKit support developers by providing a default theme for applications to maintain a consistent user interface, at least design and color wise. Despite the statement of Wessels, Purvis, Rahman (2011) that a consistency to a desktop application should be maintained¹²⁶, we focused on an easy to use user interface on mobile devices. Some parts look very familiar on both applications, e.g. the detailed informations or the comparison of pharmaceuticals, but the navigation is absolutely different as a result of the limited screen size and a touch- instead of mouse-based operation. We chose this differentiation with the statement of Lica (2010) in mind that the mobile app should only provide enough functionality to be useful¹²⁷. This resulted likewise in a missing customizable tab-bar or different sidebars. These elements might be operational on a bigger screened device such as tablets, but it is not useable on most mobile phones.

¹²⁶ cf. Wessels, Purvis, Rahman (2011), p. 1067

¹²⁷ cf. Lica (2010), p. 66

Further development of the mobile app might develop an optimized tablet user interface and integrate this functionality.

In sections 4.3 The Planning Process and 4.4 The Implementation Process we stated that we utilized a navigation bar and a toolbar as main interaction controls for navigation and direct interaction such as clearing lists. These two concepts of placing controls on the edges of the screen are also recommended by World Wide Web Consortium (2008)¹²⁸.

We also tried to follow common input methods. Because we did not have specific input fields for e.g. numbers, the only specialization we could use was the enter-key equivalent on mobile devices, often a button on the lower right corner of the simulated on-screen keyboard.

World Wide Web Consortium (2008) suggested a "Default Delivery Context"¹²⁹ illustrated in Tab. 4-1 Mobile Default Delivery Context for Mobile Optimized Applications. Vaadin does not leave much to the developer to optimize the rendering of the controls as well as the organization of requests and client-side handling of data. Developers can only optimize used images and CSS style sheets. Because only very few images are used and not much custom styling is applied, we could not pursue this recommendation in particular.

Comparing this app to the Three Layers Design Guideline developed by Ayob, Nurul Zakiah binti, Hussin, Ab Razak Che, Dahlan (2009), illustrated in Tab. 4-2 Three Layers Design Guideline for Mobile Application, results in the following: While phase one, the analysis, was already done by Dehling, Sunyaev (2012a), phase two was one of the purposes of this thesis. We tried to implement shortcuts where possible with the help of toolbars and quick access to settings, specially in the detail view, and offered where possible informative feedback, e.g. for the search right beneath the input field or in popovers for detailed information. Using the same theme and general user interface layout led to the proposed consistency as well as the optimization for small devices. The utilization of a navigation bar at the top also compiles with the proposed "top-down" interaction or navigation. Vaadin as framework as well as the already existing code support error prevention or simple handling of those. Personalization is made possible with the settings

¹²⁸ cf. World Wide Web Consortium (2008), 8.

¹²⁹ cf. World Health Organization (2011), 3.7 Default Delivery Context

view which enables the user to select only those information to be displayed he is interested in.

Phase three, testing, could only be done superficially until the end of this thesis' time frame. Further development might pursue a more detailed testing of the mobile app.

The internal requirements were compiled with mostly, buttons were made salient and interaction with them resulted in immediate feedback. For instance, the search button disables itself until the server processed the request hence the user cannot execute the search twice. The mobile app is available on nearly any mobile platform thanks to the HTML 5 standard and its good distribution among current browsers. Also, the app is as modular as the web client because much code was reused and mostly only adapted to the changes in Vaadin 7 compared to Vaadin 6 and the layout which was optimized for small screens. Only the color scheme was not adapted because of the already addressed more general familiarity among mobile OS with the default theme.

Validating the app from an overall point of view, we propose that further development of the client may lead to an even more effective use for the user with a focus on an optimization in the details, especially for the basic theme. We would set the focus on the popovers which are currently not matching perfectly to the overall appearance. Nevertheless, the mobile app follows the guidelines stated in section 4.1 Preconditions and should provide a good user interface and functionality. A dedicated usability test may reveal some remaining weak points.

5. Lessons Learned

We learned very different lessons during development. mHealth apps do have some similar requirements as any app, but have to deal with much stronger information security concerns compared to casual apps. They also need to pay more attention to usability and availability than casual apps by definition.

In the case of ePill information security is not an issue because no user related information is stored and with the web-based mobile app ePill is available on nearly any mobile device. But developing with Vaadin as framework was not always a good choice. Vaadin simplified the development process but slowed down at the very beginning and had a price to pay: The app is not as perfectly designed as it could have been with more influence on the client-side, especially on the user interface in terms of available controls.

Starting with Vaadin is not really hard but takes some time to getting started. We had some trouble getting started with Vaadin's installation because our installed version of Eclipse IDE¹³⁰ was not compatible, the same happened to our installed version of Maven. After having read the Vaadin's Beginner Guide¹³¹ we only had minor issues understanding Vaadin's architecture and development went mostly quick and easy. As already stated, some missing controls were a drawback to us and workarounds had to be found, but all in all it is a good solution for a quick development without the need of further knowledge in HTML, CSS or JavaScript. Having not to deal with cross-browser-optimizations was a relieve.

After the development of the mobile app we would nevertheless propose a different approach. If Vaadin is already utilized in the existing system, it is good to reuse the code. But if not, or if a web service is available, we would propose native applications, maybe developed with Xamarin¹³². This offers the possibility to fine tune the user interface much more, offer a much more familiar look on the different OS and much more controls are available. It is worth the additional effort of developing a web service and different user interfaces, at least their OS-specific definition for the better accessibility and extended

¹³⁰ <http://eclipse.org>

¹³¹ <https://vaadin.com/tutorial>

¹³² <http://xamarin.com>

controls. Additionally, OS like iOS offer native apps the possibility to run in background and perform specific tasks energy efficiently, while web-based apps are forced to quit on exit. This constraint does not affect ePill but e.g. monitoring apps need a continuing execution.

Frameworks such as PhoneGap¹³³ provide accessibility to extended functionality of the device for most mobile OS but still do not offer background execution.

Using native apps also eases the integration of accessibility features such as font enlargement or voice guided navigation inside the app. Most modern OS provide many accessibility features which can not or only partially be utilized inside a web-based app.

We furthermore learned that planning plays an (if not the most) important role for a fast and successful implementation. For a successful planning, knowledge of the frameworks and their possibilities is a must. During planning we had only superficial knowledge about Vaadin and TouchKit, we saw some sample code and user interfaces, which made us believe that most (if not all) controls from native applications can be utilized as well. If we knew during development that many controls are not implemented already, our planned user interface would have looked different and we would have saved some time during the implementation.

6. Conclusion

This thesis aimed to state different best practices and guidelines and explain, based on a mobile prototype, how those can be implemented.

We collected existing best practices, guidelines and norms for mobile apps as well as specific ones for mHealth apps. For a discussion we performed a short literature review as stated in 4.1.2 Best Practices. All found were discussed and their importance was rated for the ePill project. This review showed that not many guidelines or theoretical development frameworks specialized on mHealth apps or even more general mobile apps are available and that some guidelines are in need for revision.

We explained the different phases we passed during the development and stated our experiences. Some of the different available frameworks were introduced and discussed. We gave reasons for our choice for Vaadin and TouchKit.

The app developed during this thesis corresponds to the requirements developed in sections 4.1 Preconditions, 4.2 Analysis and 4.3 The Planning Process. All modifications or deviations were discussed and explained. The developed app contains all needed functionality and has a mobile optimized user interface which is available on nearly any modern mobile device.

A possible point of criticism is that we did not have the time for concentrating on fine tuning and deep testing of the mobile app. Especially the missing knowledge of Vaadin and TouchKit resulted in a user interface planning which was not accurate enough. We had to find workarounds for the mentioned missing controls we integrated in our planning. This was a time consuming process we could have had avoided with more knowledge. Those workarounds could be further improved.

Adding and rating the subgoals, we come to the conclusion that this thesis' goal is achieved and that we gave not only an overview about the current state of guidelines for mHealth apps, but also developed a functional prototype of a mobile frontend for the ePill web application.
